(54) Title: NOVEL COMPOUNDS			
(57) Abstract			
<p>Heterochimeric proteins or immunogenic derivatives thereof are described comprising immunogenic fragments of RSV, PIV1, PIV2, PIV3, MV and MuV fusion and attachment glycoproteins. Such heterochimeric proteins may be expressed, in particular, in CHO cells and may be used in vaccine compositions to treat respiratory disorders such as those caused by paramyxoviridæ viral antigens.</p>

Novel Compounds

The present invention relates to recombinant heterochimeric paramyxoviridae glycoproteins and their expression in eukaryotic cells, particularly in Chinese

5 Hamster Ovary (CHO) cells. The invention further relates to methods for constructing and expressing such heterochimeric proteins, intermediates for use therein, methods to optimize the codon usage of the nucleic acid sequences which encode such heterochimeric proteins and the use of the recombinant proteins as vaccines for the prevention of diseases caused by paramyxoviridae pathogens.

10

The mumps (MuV), Measles (MV), the parainfluenza type I (PIV1), type II (PIV2) and type III (PIV3) and the respiratory syncytial (RSV) virus belong to the paramyxoviridae family. The MuV is classified in the rubulavirus subclass, the MV is classified in the Morbillivirus subclass, the parainfluenza viruses (PIV1, PIV2 15 and PIV3) are classified in the paramyxovirus subclass while the RSV is attached to the pneumovirus subclass.

20

RSV is the most important cause of viral lower respiratory tract disease in infants and children. The fusion (F) and the attachment (G) protein which are both viral surface glycoproteins appear to be of potential value for the development of a vaccine against RSV.

25

The fusion protein F of RSV contains 574 amino acid residues; amino acids 1 to 21 correspond to the signal peptide and residues 525 to 549 to the membrane anchor domain. The molecule presents five potential sites for glycosylation. The F protein is synthesized as a 70 kDa precursor (F_0) which undergoes proteolytic maturation to yield the F_1 subunit (48 kDa) and F_2 (23 kDa) linked via disulfide bridges. The protein F, when injected into animals, leads to the production of neutralizing antibodies and may induce cytotoxic lymphocytes (CTLs).

30

The attachment or G protein of RSV contains 298 amino acid residues and is heavily glycosylated since half of its molecular mass (90 kDa) is contributed by

oligosaccharide side chains, chiefly in the form of O-linked sugars. It has been shown that the G protein, when injected into animals, provides protection against homologous but not heterologous subgroup virus challenge. This protein is extremely variable and there is only a stretch of 13 amino acid residues which is 5 conserved in all RSV.

The PIV3 is second to RSV as a major agent of severe viral respiratory tract infections in infants. The fusion protein F of PIV3 contains 539 amino acid residues; amino acids 1 to 18 correspond to the signal peptide and residues 494 to 10 516 to the membrane anchor domain. The molecule presents 4 potential sites for glycosylation. The F protein is synthesized as a 70 kDa precursor (F_0) which undergoes proteolytic maturation to yield the F_1 (56 kDa) and F_2 (14 kDa) subunits linked via disulfide bridges. The protein F, when injected into animals, leads to the production of neutralizing antibodies. The F protein is involved in cell fusion during 15 viral infection and carries an hemolysin activity. Used alone for immunization, the F protein generates an immune response which is insufficient to confer protection against a challenge with the virus. Complete protection is only acquired by concomitant immunization with the attachment protein HN, another glycoprotein of PIV3.

20

The protein HN carries hemagglutinin and neuraminidase activities. It is composed of 572 amino acids; its membrane anchor domain occurs in the N-terminal end of the molecule, between amino acid residues 32 and 53. Four potential sites for glycosylation have been identified. Injection of protein HN into animals generates 25 an immune response and neutralizing antibodies. These antibodies however do not protect completely against a challenge with the virus. Full protection is obtained only by concomitant immunization with the F protein of PIV3.

The PIV1 virus was initially isolated from young children suffering from disorders 30 of the lower respiratory tract. Infection with PIV1 causes the majority of cases of croup found for all infections caused by paramyxoviruses. Viral transmission of

PIV1 is by person to person contact or by aerosol, although the virus does not persist in the environment for long.

Like PIV2 and PIV3, the PIV1 virus has two surface glycoproteins, the fusion

- 5 protein (F) and the attachment protein (HN). These two proteins are the priority targets for the development of a subunit vaccine, the properties of which would be to ensure protection of children from the very first months of life and to prevent reinfection, or at least to prevent the serious complications by restricting viral development to the upper respiratory tract where the consequences would be benign
10 (common cold).

PIV2 also affects very young children and causes the same type of respiratory discorders, essentially croup, but of less severity. The PIV2 virus has two surface glycoproteins (F and HN), which are potential targets for the development of a
15 subunit vaccine.

The measles virus is an extremely contagious agent which establishes itself in the epithelial cells of the respiratory tract, the oropharynx or the conjunctiva. The infection causes fever, cough, head-cold, conjunctivitis and a characteristic
20 generalised rash.

There is no appropriate inactivated vaccine against measles but an effective attenuated live vaccine is available and is generally used in combination with the attenuated live vaccines against rubella and mumps. This live vaccine protects
25

- against the disease for at least 20 years. The measles virus has two surface glycoproteins, which are potential targets for the development of a subunit vaccine. The fusion protein (F) is a 550 amino acid long glycosylated molecule and, as for the other paramyxovirus, has to undergo proteolitic cleavage to yield F₁ and F₂ subunits that are linked via disulfide bridges. This molecule, which carries a
30 haemolysin activity, generates an immune protective response when injected into animals. The attachment protein (H), is a 617 amino acid long glycosylated protein, which carries a hemagglutinin activity. This protein leads, when injected into

animals, to the production of neutralizing antibodies that are able to inhibit hemagglutination. This immune response protects the animal against a viral challenge.

- 5 The mumps virus is a pathogen causing the contagious infantile illness which consists of the inflammation of parotid glands. During the incubation period following infection, the virus replicates in the respiratory epithelium then disseminates into secretory ducts of the parotid glands. Other glands may become infected thereafter and numerous cases of meningitis have been reported. Among
10 complications related to the infection, encephalitis is a serious one, with a mortality rate of about 1%; deafness cases have also been reported.

A vaccine against mumps is available: it is made of an attenuated live virus, produced by culturing infected embryonic chicken cells. The vaccine leads to the
15 seroconversion in vaccinated individuals and protects against infection in more than 95% of seronegative persons. The vaccine thus reduces significantly the frequencies of complications.

In a number of cases, however, viral infection is not detected because the effects
20 remain subclinical. Young children and aged people are most likely to develop complications from mumps infection. In view of the inherent risks related to the use of attenuated live vaccines, such as the potentiation of the illness upon natural surinfection in vaccinated individuals, it is desirable to improve the safety of the vaccine, particularly for the groups at risk.

25

The fusion protein F of mumps virus contains 538 amino acid residues; amino acids 1 to 26 correspond to the signal peptide and residues 483 to 512 to the membrane anchor domain. The molecule presents 7 potential sites for glycosylation. The F protein is synthesized as a 65-74 kDa precursor (F_0) which undergoes proteolytic
30 maturation to yield the F_1 (58-61 kDa) and F_2 (10-16 kDa) subunits linked via disulfide bridges. The protein F is involved in cell fusion during viral infection, carries an haemolysin activity and plays a role for viral penetration into cells. It

does not however carry the antibody dependent cellular cytotoxicity (ADCC) as observed for another mumps virus glycoprotein, HN.

The protein HN (molecular weight 74-80 kDa) carries hemagglutinin and
5 neuraminidase activities which are involved in virus attachment to cells and in the disruption of the host cell membranes. Protein HN (attachment protein or hemagglutinin-neuraminidase) generates neutralizing antibodies and appears important for the development of ADCC. Protein HN is composed of 582 amino acids; it carries a N-terminal anchor domain (residues 33 to 52) and 9 potential sites
10 for glycosylation.

For the viruses considered above, it appears that concomitant immunization with both membrane glycoproteins F and HN, or G in the case of RSV, are required to achieve full protection in the animal model. Chimeric proteins containing both the F
15 and G proteins of RSV, or the F and HN proteins of PIV3 have shown complete protection against RSV or PIV3 challenge in cotton rats (Brideau et al, J Gen Virol, 1989, 70 2637-2644 and Brideau et al, J Gen Virol, 1993, 74, 471-477).

WO9314207 (Connaught) describes heterochimeric proteins comprising RSV and
20 PIV3 proteins including F(RSV)xHN(PIV3) and F(PIV3)xG(RSV) hybrids, and suggests that such proteins can be expressed from a variety of host cells including bacterial, mammalian, insect, yeast and fungal cells. The specific examples describe expression in insect Sf9 and High 5 cells and mammalian Vero cells.
There is no specific disclosure of the use of CHO cells. The use of Sf9 and High 5
25 cells is also described by Du et al, BIO/TECHNOLOGY 12,1994, 813-818.

Homa et al (Upjohn), J Gen Virol, 1993, 74, 1995-1999 describes another heterochimeric protein, F(RSV)xHN(PIV3) expressed in insect cells using a recombinant baculovirus.

30

Homochimeric paramyxoviridae glycoproteins have also been described by several workers:-

WO8905823 (Upjohn) describes RSV FxG and GxF hybrids which can be expressed from bacterial, yeast, mammalian and insect cells. Example 7 describes the expression of an RSV FxG protein from CHO cells although there are no details of
5 how successful such expression is.

WO8910405 (Upjohn) describes PIV3 FxHN and HNxF hybrids which can be expressed from bacterial, yeast, mammalian and insect cells. Example 6 describes the expression of a PIV3 FxHN protein from CHO cells, however no details are
10 given quantifying the extent of expression and secretion.

Lehman et al (Upjohn), J Gen Virol, 1993, 74, 459-469 describes the expression of PIV3 FxHN in insect cells using recombinant baculovirus vectors as well as in CHO cells.

15 WO9306218 (SmithKline Beecham Biologicals) describes PIV3 FxHN hybrids which can be expressed in eukaryotic cells including vaccinia, CHO or Vero cells. Example B)2 describes the expression of a $Fs^+a^-xHNa^-$ hybrid in CHO cells and indicates that the product was almost evenly distributed between cells and medium.
20 No details are however given quantifying the extent of expression and secretion.

WO9425600 (SmithKline Beecham Biologicals) describes MuV FxHN and HNxF hybrids which can be expressed in vaccinia, a mammalian cell (such as CHO) or a bacterial cell. Examples B) 3 and 4 describe the expression of $s^+FHNa^-xFa^-$ and
25 $Fs^+a^-xHNa^-$ in CHO cells however no details are given describing the extent of expression and secretion.

Although this cited art may suggest that homochimeric paramyxoviridae glycoproteins can be expressed in a variety of cell lines including CHO cells it has
30 now been discovered that in fact expression and secretion from CHO cells is not always successful and success cannot be predicted. Thus it has now been demonstrated that although a RSV F x G hybrid could be successfully expressed and

secreted in CHO cells, analogous homochimeric hybrids from PIV3 and MuV could not in fact be expressed in CHO cells in such manner that they could be purified from the supernatant in significant quantities.

- 5 Surprisingly, it has now been discovered that heterochimeric hybrids can be successfully expressed and secreted in both CHO and insect cells.

Accordingly in a first aspect the present invention provides a process for preparing a heterochimeric protein or an immunogenic derivative thereof comprising an 10 immunogenic fragment of the fusion (F) protein of RSV, PIV1, PIV2, PIV3, MV or MuV and an immunogenic fragment of the attachment (G, HN or H) protein of RSV, PIV1, PIV2, PIV3, MuV or MV which process comprises expressing recombinant DNA encoding the heterochimeric protein or immunogenic derivative thereof in CHO cells and recovering the protein.

- 15 By heterochimeric protein is meant one that does not contain a fusion or attachment protein from the same pathogen.

This invention also provides novel heterochimeric proteins not previously described 20 in WO 9314207 which can be prepared using the process of the present invention.

Thus, in a second aspect the present invention provides a heterochimeric protein or an immunogenic derivative thereof comprising an immunogenic fragment of the fusion (F) protein of RSV, PIV1, PIV2, PIV3, MV or MuV and an immunogenic 25 fragment of the attachment (G, HN or H) protein of RSV, PIV1, PIV2, PIV3, MuV or MV, with the proviso that where one of the immunogenic fragments is derived from RSV F, RSV HN or PIV3 F, PIV3 HN, the other of the immunogenic fragments is derived from MuV F, MuV HN, MV F, MV H, PIV1 F, PIV1 HN, PIV2 F or PIV2 HN.

- 30 By an immunogenic fragment of the fusion (F) protein of RSV, PIV1, PIV2, PIV3, MV or MuV is meant a part of the protein which contains at least one antigenic

determinant capable of raising an immune response specific to the F protein of RSV, PIV1, PIV2, PIV3, MV or MuV respectively. Included within this definition is the full length F protein, preferably however the immunogenic fragment is lacking the membrane anchor domain at its C-terminal end.

5

By an immunogenic fragment of the attachment protein (G, HN or H) of RSV, PIV1, PIV2, PIV3, MuV or MV is meant a part of the protein which contains at least one antigenic determinant capable of raising an immune response specific to the G protein of RSV, to the HN protein of PIV1, PIV2, PIV3, MuV or the H protein of MV respectively. Included within this definition is the full length G or HN protein, preferably however the immunogenic fragment is lacking the signal/anchor domain at its N-terminal end.

Preferably the heterochimeric protein is linked *via* an amino acid in the C-terminal part of the immunogenic fragment of the F protein of RSV, PIV1, PIV2, PIV3, MV or MuV to an amino acid in the N-terminal part of the immunogenic fragment of the G protein of RSV, the HN protein of PIV1, PIV2, PIV3, MuV or the H protein of MV.

20

Suitably the heterochimeric protein commences at its N-terminal end with a signal sequence from the F protein of RSV, PIV1, PIV2, PIV3, MV or MuV. Conveniently this will be part of the corresponding immunogenic fragment of the F protein of RSV, PIV1, PIV2, PIV3, MV or MuV when this fragment is linked *via* its C-terminal end to the N-terminal end of the immunogenic fragment of the G protein of RSV, the HN protein of PIV1, PIV2, PIV3, MuV or the H protein of MV.

25

Alternative signal sequences may also be employed. For example, the heterochimeric protein suitably commences at its N-terminal end with a signal sequence of tissue plasminogen activator (TPA).

30

In order to enhance the level of expression the heterochimeric protein may further comprise a ubiquitin leader sequence which is suitably positioned after any signal sequence as hereinbefore described. Preferably the ubiquitin leader sequence is linked to the C-terminal end of the signal sequence of TPA.

5

Preferably the ubiquitin leader sequence is derived from yeast, for example as described in Ecker et al, J.Biological Chemistry, 1988, 264(13), 7715-7719.

Suitably a cleavage site is positioned between the C-terminal end of the ubiquitin

- 10 sequence and the N-terminal end of the immunogenic fragment of the F protein of RSV, PIV1, PIV2, PIV3, MV or MuV.

In order to facilitate chromatographic purification the heterochimeric protein suitably comprises a polyhistidine tail, for example as described in Hochuli et al,

- 15 BIO/TECHNOLOGY, 1988, 1321-1325. The polyhistidine tail preferably comprises from 2 to 6 adjacent histidine residues which is suitably attached at the C-terminal end of the heterochimeric protein. Preferably a cleavage site is positioned between the polyhistidine tail and the C-terminal end of the immunogenic fragment of the G protein of RSV, the HN protein of PIV1, PIV2, PIV3, MuV or the H protein of MV.

The cleavage site for the ubiquitin sequence and/or the polyhistidine tail may be chemical or enzymatic and preferably is an enterokinase cleavage site, for example as described in LaVallie et al, BIO-TECHNOLOGY, 1993, 187-193.

25

Following expression and purification, treatment with an enterokinase will cleave off any ubiquitin and/or polyhistidine sequence releasing the desired heterochimeric protein.

- 30 Particular heterochimeric proteins of this invention include:
the F protein of RSV lacking its membrane domain linked at its C-terminal end to the HN protein of MuV lacking its signal/anchor domain herein referred to as:

F_s⁺a⁻RSVxHNs⁻a⁻MuV, as well as
F_s⁺a⁻PIV3 x HNs⁻a⁻MuV;
F_s⁺a⁻MuV x Gs⁻a⁻RSV; and
F_s⁺a⁻MuV x HNs⁻a⁻PIV3, and
5 immunogenic derivatives thereof.

The present invention also provides particular heterochimeric proteins which include:

F_s⁺a⁻MuVxHs⁻aMV; or
10 F_s⁺a⁻RSVxHNs⁻a⁻PIV1; or
F_s⁺a⁻RSVxHNs⁻a⁻PIV2, and
imunogenic derivatives thereof.

The present invention also provides heterochimeric proteins comprising RSV and
15 PIV3 proteins not specifically disclosed in WO9314207, which advantageously can
be expressed from CHO cells.

These are:

F_s⁺a⁻(1-526) RSV x HNs⁻a⁻(70-572) PIV3;
F_s⁺a⁻(1-492) PIV3 x Gs⁻a⁻(69-298) RSV;
20 F_s⁺a⁻(1-526) RSV x HNs⁻a⁻(70-572) PIV3 bis;
F_s⁺a⁻(1-526) RSV x HNs⁻a⁻(70-572) PIV3 ent his, and
sTPA (1-21) UB (1-74) ent F_s⁺a⁻(24-526) x HN s⁻a⁻(70-572) PIV3, and
immunogenic derivatives thereof.

25 The heterochimeric proteins of the present invention are immunogenic. The term immunogenic derivative as used herein encompasses any molecule which is a heterochimeric polypeptide which is immunologically reactive with antibodies raised to the heterochimeric protein of the present invention or parts thereof or with antibodies recognising the F protein of RSV, PIV1, PIV2, PIV3, MV or MuV, the
30 G protein of RSV, the HN protein of PIV1, PIV2, PIV3, MuV, the H protein of MV, the RSV virus, the PIV1 virus, the PIV2 virus, the PIV3 virus, the MV virus or the MuV virus, or which, when administered to a human, elicits antibodies

recognising the F protein of RSV, PIV1, PIV2, PIV3, MV or MuV, the G protein of RSV, the HN protein of PIV1, PIV2, PIV3, MuV, the H protein of MV, the RSV virus, the PIV1 virus, the PIV2 virus, the PIV3 virus, the MV virus or the MuV virus. In particular immunogenic derivatives which are slightly longer or
5 shorter than the heterochimeric proteins of the present invention may be used. Such derivatives may, for example, be prepared by substitution, addition, or rearrangement of amino acids or by chemical modifications thereof including the coupling or for enabling the coupling of the heterochimeric proteins to other carrier proteins such as tetanus toxoid or Hepatitis B surface antigen. All such substitutions
10 and modifications are generally well known to those skilled in the art of peptide chemistry.

Immunogenic fragments of the heterochimeric proteins which may be useful in the preparation of vaccines may be prepared by expression of the appropriate gene
15 fragments or by peptide synthesis, for example using the Merrifield synthesis (The Peptides, Vol 2., Academic Press, New York, p3).

In a further aspect of the invention there is provided recombinant DNA encoding the heterochimeric protein of the invention. The recombinant DNA of the invention
20 may form part of a vector, for example a plasmid, especially an expression plasmid from which the heterochimeric protein may be expressed. Such vectors also form part of the invention, as do host cells into which the vectors have been introduced.

In order to construct the DNA encoding a heterochimeric protein according to the
25 invention, cDNA containing the coding sequences of the RSV, PIV1, PIV2, PIV3, MV or MuV fusion and attachment proteins and optionally of the ubiquitin, polyhistidine and enterokinase cleavage sites may be manipulated using standard techniques [see for example Maniatis T. et al Molecular Cloning, Cold Spring Harbor Laboratory, Cold Spring Harbor N.Y. (1982)] as further described
30 hereinbelow.

In another aspect of the invention there is described a process of enhancing the protein expression in mammalian cells by optimization of the codon usage of the nucleic acids transfected therein. Optimization of the codon usage involves the replacement of at least one non-preferred or less preferred codon in a natural gene

5 encoding a heterochimeric protein by a preferred codon encoding the same amino acid. Highly mammalian-expressed genes have C or G at their degenerative position (third base in the codon) whereas the RSV or PIV3-prevalent codons have A or T. At least one codon, and more preferably all the codons of the RSV or PIV3 protein can be changed to fit at best the human usage, that is, the one (or

10 ones) that is the most prevalent as shown below.

Ala: GCC	Cys: TGC	His: CAC	Met: ATG	Thr: ACC
Arg: CGC AGG CGG	Gln: CAG	Ile: ATC	Phe: TTC	Trp: TGG
Asn: AAC	Glu: GAG	Leu: CTG	Pro: CCC	Tyr: TAC
Asp: GAC	Gly: GGC	Lys: AAG	Ser: AGC TCC	Val: GTG

15 Each amino acid encoded by one of these codons are then considered humanised. The ratio between the number of humanised codons versus the total number of amino acids gives a percentage of humanisation as shown below.

- | | | |
|----|---|-------------------|
| 1) | $F_{RSV\ (1-526)\text{original}}$ | $140/526 = 27\%$ |
| 20 | $F_{RSV\ (1-423)\text{humanised}} + (424-526)\text{original}$ | $403/526 = 77\%$ |
| 3) | $F_{RSV\ (1-526)\text{humanised}}$ | $489/526 = 93\%$ |
| 4) | $F_{RSV\ (1-526)\text{original}} + HN_{PIV3\ (70-572)\text{ original}}$ | $258/1029 = 25\%$ |
| 5) | $F_{RSV\ (1-526)\text{humanised}} + HN_{PIV3\ (70-572)\text{ original}}$ | $528/1029 = 51\%$ |
| 6) | $F_{RSV\ (1-526)\text{humanised}} + HN_{PIV3\ (70-572)\text{ humanised}}$ | 96% |

The invention also provides DNA encoding a heterochimeric protein or immunogenic derivative thereof in which the codon usage of one or more nucleic acids has been substantially optimised and a process for expressing said DNA in a CHO or insect cell.

5

There have been a number of reports that have described a substantial amelioration of protein expression in mammalian cells after re-engineering the nucleic acid sequence of the heterologous protein to fit the codon usage found in highly expressed human genes (Haas J., Park E-C. and Seed B., Codon usage limitation in

10 the expression of HIV-1 envelope glycoprotein, Current Biology, 1996, 6, n°3, 315-325 ; Kim C. H., Oh Y. and Lee T.H., Codon optimization for high-level expression of human erythropoietin (EPO) in mammalian cells, Gene 199, 1997, 293-301 ; Zolotukhin S., Potter M. Hauswirth W.W. Guy J. and Muzyczka N. A Humanized green fluorescent protein cDNA adapted for high level expression in
15 mammalian cells. J. of Virology, July 1996, 70, n°7, 4646-4654).

Vectors comprising such DNA, hosts transformed thereby and the truncated or hybrid proteins themselves, expressed as described hereinbelow all form part of the invention.

20

For expression of the proteins of the invention, plasmids may be constructed which are suitable either for transfer into vaccinia virus or transfection into CHO cells, insect cells or Vero cells. Suitable expression vectors are described hereinbelow. Preferably the proteins of the present invention are expressed in CHO or insect
25 cells.

For expression in vaccinia a vaccinia transfer plasmid such as pULB 5213 which is a derivative of pSC11 (Chakrabati *et al*, Molecular and Cellular Biology 5, 3403 - 3409, 1985) may be used. In one aspect the protein may be expressed under the
30 control of the vaccinia P_{7.5} promoter.

For expression in CHO-K1 cells a glutamine synthetase (GS) vector such as pEE14 may suitably be used so that the protein is expressed under the control of the major immediate early promoter of human cytomegalovirus (hCMV-MIE). Alternatively a vector which allows the expression of the coding module as a polycistronic

- 5 transcript with the *neo* selection gene may suitably be used. In one preferred aspect the coding module is under the control of the Rous Sarcoma Long Terminal Repeat (LTR) promoter.

Preferably the plasmid for expression in CHO-K1 cells carries a GS expression

- 10 cassette suitable for gene amplification using methionine sulphoximine (MSX).

Alternatively the plasmid for expression in CHO-K1 cells carries a DHFR expression cassette suitable for gene amplification using methotrexate (MTX).

Preferably expression of the heterochimeric protein of the present invention is

- 15 carried out in the presence of sodium butyrate and/or dimethyl sulphoxide (DMSO) which may enhance gene expression.

For expression in insect cells a shuttle vector such as pAcUW51 or pAcGP67 may

be used. In one aspect the protein may be expressed under the control of the

- 20 baculovirus p10 promoter or the polyhedrin promoter.

The expression system may also be a recombinant live microorganism, such as a virus or bacterium. The gene of interest can be inserted into the genome of a live recombinant virus or bacterium. Inoculation and *in vivo* infection with this live vector

- 25 will lead to *in vivo* expression of the antigen and induction of immune responses.

Viruses and bacteria used for this purpose are for instance: poxviruses (e.g; vaccinia, fowlpox, canarypox), alphaviruses (Sindbis virus, Semliki Forest Virus, Venezuelan Equine Encephalitis Virus), adenoviruses, adeno-associated virus, picornaviruses (poliovirus, rhinovirus), herpesviruses (varicella zoster virus, etc), Listeria, Salmonella,

- 30 Shigella, BCG. These viruses and bacteria can be virulent, or attenuated in various ways in order to obtain live vaccines. Such live vaccines also form part of the invention.

In yet another aspect of the invention there is provided a vaccine composition comprising a heterochimeric protein or immunogenic derivative thereof according to the invention in combination with a pharmaceutically acceptable carrier, a protein
5 according to the invention for use in vaccinating a mammal and the use of a protein according to the invention in the preparation of a vaccine.

Optionally, and advantageously, the vaccine of the present invention is combined with other immunogens to afford a polyvalent vaccine. In a preferred embodiment
10 the heterochimeric protein is combined with other subcomponents of RSV, PIV1, PIV2, PIV3, MuV or MV, e.g. the single proteins F, G, HN or H or homochimeric proteins such as RSV FxG, PIV3 FxHN or MuV FxHN.

In a particular aspect the invention further provides a vaccine composition
15 comprising a protein according to the invention together with a suitable carrier or adjuvant.

Vaccine preparation is generally described in *New Trends and Developments in Vaccines*, edited by Voller *et al*, University Park Press, Baltimore, Maryland,
20 U.S.A., 1978. Encapsulation within liposomes is described, for example by Fullerton, U.S. Patent 4,235,877.

In the vaccine of the present invention , an aqueous solution of the protein(s) can be used directly. Alternatively, the protein, with or without prior lyophilisation, can
25 be mixed, absorbed or adsorbed with any of the various known adjuvants. Such adjuvants include, but are not limited to, aluminium hydroxide, muramyl dipeptide and saponins such as Quil A. Particularly preferred adjuvants are MPL (monophosphoryl lipid A) and 3D-MPL (3 deacylated monophosphoryl lipid A) [US patent 4,912,094], optionally formulated with aluminium hydroxide (EP 0 689 454)
30 or oil in water emulsions (WO 95/17210). A further preferred adjuvant is known as QS21 which can be obtained by the method disclosed in US patent 5,057,540. Use of 3D-MPL is described by Ribi *et al.* in *Microbiology* (1986) Levie *et al.* (eds)

Amer. Soc. Microbiol. Wash. D.C., 9-13. Use of Quil A is disclosed by Dalsgaard *et al.*, (1977), Acta Vet Scand, 18, 349. Use of combined 3D-MPL and QS21 is described in WO 94/00153 (SmithKline Beecham Biologicals s.a). QS21 may be advantageously formulated with cholesterol containing liposomes, wherein 3D-MPL 5 is present either in solution or incorporated in the membrane, as described in WO 96/33739.

As a further exemplary alternative, a heterochimeric protein of the invention or an immunogenic fragment thereof can be encapsulated within microparticles such as 10 liposomes or associated with oil-in-water emulsions. Encapsulation within liposomes is described by Fullerton in US patent 4,235,877. In yet another exemplary alternative, a heterochimeric protein according to the invention or an immunogenic fragment thereof can be conjugated to an immunostimulating macromolecule, such as killed *Bordetella* or a tetanus toxoid. Conjugation of 15 proteins to macromolecules is disclosed, for example by Likhite in patent 4,372,945 and Armor *et al.* in US patent 4,474,757.

The amount of the protein of the present invention present in each vaccine dose is selected as an amount which induces an immunoprotective response without 20 significant, adverse side effects in typical vaccines. Such amount will vary depending upon which specific immunogen is employed and whether or not the vaccine is adjuvanted. Generally, it is expected that each dose will comprise 1-1000 μ g of protein, preferably 1-200 μ g. An optimal amount for a particular vaccine can be ascertained by standard studies involving observation of antibody 25 titres and other responses in subjects.

The following examples and the attached figures (explained below) illustrate the invention.

30 **In the Figures:**

Figure 34A shows the impact of humanisation on the level of expression of FrHNp, where:

FhHNE10 = product expressed by the pEE14FhHN transfected clone E10;

FhHNE7 = product expressed by the pEE14FhHN transfected clone E7;

FHNbis = product expressed by the pEE14FHN transfected clone;

+but = 2mM Nabutyrate has been added to the cell medium, 3 days before

5 harvest;

pEE14 = negative control;

Fdros0 = pruified Fa- (drosophila derived); the standard protein in this ELISA assay wherein 1ul of standard corresponds to 1ng of product.

Figure 34B shows humanisation impact on the level of expression of F_{RSV}HN_{PiV3},

10 where the level of expression was determined by ELISA. Fdros0 = purified Fa- (drosophila derived) that is the standard protein in this ELISA assay, 1ul of standard corresponds to 1ng of product.

EXAMPLES

Example 1

In order to vaccinate with a single immunogen, heterochimeric DNA molecules
5 were constructed combining extracellular domains of the F and the attachment
protein for each virus. DNA constructs for the PIV3 and MuV have already been
described in WO9306218 and WO9425600, respectively. The DNA molecule
combining the extracellular domains of the RSV F and G proteins were constructed
as described below.

10

The DNA pieces were first inserted into the mammalian expression vector based on
the replicon of the Semliki Forest Virus (pSFV1). This expression system does not
lead to a stable expression mammalian cell line but, however gives an indication
whether or not the chimeric protein is expressed and whether the product is
15 effectively secreted in the culture medium, which is advantageous for the
purification procedure.

Stable expression in the culture medium of mammalian cell lines is preferred to
obtain good quality and quantities of paramyxovirus glycoproteins. All the chimeric
20 modules have been inserted in the shuttle vector, the pEE14, which integrates in the
genome of mammalian cells such as CHO-K1. A quite good expression level was
obtained with the RSV FxG homochimeric recombinant protein, however negligible
expression was obtained for the FxHN recombinant homochimeric protein of either
PIV3 or MuV. Expression of heterochimeric proteins was obtained from CHO
25 cells.

Thus by constructing heterochimeric DNA molecules combining the extracellular
domains of the F protein of one virus linked to the extra cellular domain of the HN
or G protein of another virus and inserting them into the pEE14 vector for CHO
30 expression it has been possible to raise the expression level of these proteins. These
proteins may be used to achieve protection against at least two paramyxoviridae
viruses with a single immunogen.

Some of the chimeric molecules have been inserted into the shuttle vectors, pAcUW51 and pACGP67, which integrate in the genome of bacterial and lepidopteran cells. Surprisingly good expression of heterochimeric proteins was
5 obtained from insect cells.

Vector construction

Preliminary Constructs

10

a) Plasmid pNIV2819

Starting from plasmid pNIV2801, a cDNA clone encoding *inter alia* the F protein of RSV (type RSS-2; received from Dr Pringle, UK) we reconstructed a cDNA
15 module coding for the F protein lacking the membrane anchor sequence.

Plasmid pNIV2801 was digested with *Pst*I in order to recover a 1416 bp DNA piece encoding amino acid residues 18 to 489 of the F protein. Synthetic oligonucleotides, specifying respectively the sequences for amino acids 1 to 17 and
20 490 to 526, were used to produce the corresponding cDNA fragments by the polymerase chain reaction performed with pNIV2801 DNA as template. The primers were designed to generate also unique flanking restriction sites useful for subsequent cloning steps. The coding module was assembled, by ligation, from the three DNA pieces described above and introduced into the standard cloning vector
25 pUC19, to create plasmid pNIV2819. This plasmid encodes the RSV F protein carrying its signal sequence but lacking its anchor sequence (figure 1).

b) Plasmid pNIV 2820

30 The cDNA module encoding the full length F protein of RSV was constructed as follows. Using two synthetic oligonucleotides, the polymerase chain reaction was performed with pNIV2801 DNA as template to generate a 273 bp DNA fragment

encompassing the sequence coding for aa 490 to aa 574 of the F protein, the stop codon and unique restriction sites useful for subsequent cloning steps. This fragment was digested with *NsiI* and *EcoRI* and substituted for the *NsiI-EcoRI* DNA piece present in the coding module of pNIV2819 (figure 2). The resulting plasmid,
5 pNIV2820, thus encodes the RSV F protein carrying both signal and membrane anchor sequences.

c) Plasmid pNIV2841

10 In this construction, the DNA coding for aa 165 to 176 of the G protein of RSV is fused to the DNA encoding the RSV *Fs⁺a* protein. This part of the G protein is conserved among both subgroups of RSV.

The starting material, pNIV2819, was digested by *NcoI* and *SmaI* yielding a 1601
15 bp fragment. This fragment was subcloned into the *NcoI* and *MscI* sites of pNIV103 (a derivative of pULB1221, see European Patent Application No. 186643) leading to pNIV2844. This subcloning allowed to place the translation initiation site of the F protein in a more favourable context according to the model proposed by Kozak (Kozak M, Nature 308, 241-246, 1984).

20

A 1605 bp fragment was recovered from pNIV2844 by digestion with *KpnI* and *SalI* and introduced by ligation into pUC19 digested with *KpnI* and *SalI*, creating pNIV2840.

25 Two complementary synthetic oligonucleotides specifying the sequence for amino acids 165 to 176 of the G protein followed by a stop codon and flanked by *NsiI*, *BamHI*, *EcoRI* and *HindIII* sites were hybridized. The 55 bp resulting fragment was cloned into the pNIV2840 digested by *NsiI* and *HindIII*, thus replacing a 142 bp DNA sequence encoding amino acids 491 to 526 of the F protein. The resulting
30 recombinant plasmid, pNIV2841, thus contains the sequence coding for amino acids 1 to 490 of the F protein followed by amino acids 165 to 176 of the G protein (figure 3).

Vector Construction**I) For transfer into the pSFV1 vector**

- 5 a) The RSV fusion protein lacking the membrane anchor domain fused to the
MuV hemagglutinin-neuraminidase lacking the signal-anchor domain, F_{RSV} (1-
526) HN_{MuV} (60-582).

Plasmid pNIV2875, a derivative of pNIV2820 which carries the DNA coding for
10 the F protein of RSV in which the *SpeI* restriction site has been eliminated by site-
directed mutagenesis into the pUC19 vector, has been digested by *HindIII* and
BspHI, and a 1618 bp fragment has been isolated. Plasmid pNIV3229, a derivative
of pNIV3215 whose construction has been already described in WO9425600 and
which carries the DNA coding for the HN protein of MuV into the pUC19 vector,
15 has been digested with *BbsI* and *BamHI*; a 1580 bp fragment has been isolated.
Both fragments were linked together by two complementary synthetic *BspHI-BbsI*
oligonucleotides (Fig 4A) restoring the coding sequence of the chimeric molecule
and were inserted into the *BamHI-HindIII* site of the pUC19 vector leading to
pNIV4102. (Fig4B) After the sequencing of the junction regions, the chimeric
20 cassette was retrieved from pNIV4102 by a *BamHI* digestion and was inserted into
the *BamHI* site of the pSFV1 vector (Liljeström, P. and Garoff,H. (1991)
Bio/Technology 9, 1356). The resulting plasmid, pNIV4104, contains into the
pSFV1 vector the sequence coding for amino acids 1 to 526 of the RSV F protein
followed by amino acids 60 to 582 of the MuV HN protein. (Fig4C)

25

- b) The RSV fusion protein lacking the membrane anchor domain fused to the
PIV3 hemagglutinin-neuraminidase lacking the signal-anchor domain, F_{RSV} (1-
526) HN_{PIV3} (70-572).

- 30 Plasmid pIBI-HN , a cDNA clone containing the complete coding sequence of
protein HN of PIV3 as well as its 3' non coding sequence (received from Dr.K.
Dimock, University of Ottawa, Canada), has been digested by *AseI* and *BamHI* and

- a 1468 bp fragment has been isolated. Plasmid pNIV2875 (see supra), which carries the DNA encoding the F protein of RSV, in which the unique *SpeI* site has been eliminated by site-directed mutagenesis, inserted into the pUC19 vector, has been digested by *BamHI* and *BspHI*, and a 1588 bp fragment has been isolated. Both 5 fragments were linked together by two complementary synthetic *BspHI-AseI* oligonucleotides (Fig5A) and were inserted into the *BamHI* site of the pUC19 vector leading to pNIV4105 or to pNIV4109 (Fig5B) depending of the orientation of the chimeric module in the vector. After the sequencing of the junction region, the chimeric cassette was retrieved by a *BamHI* digestion from pNIV4109 and inserted 10 into the *BamHI* site of the pSFV1 vector. The resulting plasmid, pNIV4110, contains, inserted into the pSFV1 vector, the sequence coding for amino acids 1 to 526 of the RSV F protein followed by amino acids 70 to 572 of the PIV3 HN protein. (Fig5C)
- 15 c) The PIV3 fusion protein lacking the membrane anchor domain fused to the RSV attachment protein lacking the signal-anchor domain, F_{PIV3} (1-492) G_{RSV} (69-298).

Plasmid pNIV3310, described in WO9306218 which carries the DNA coding for 20 amino acids 1 to 484 of the PIV3 F protein followed by amino acids 87 to 572 of the PIV3 HN protein into the pIBI vector, was digested by *EcoRI* and *BglII*, and a 1435 bp fragment has been isolated. Plasmid pNIV2850, which carries the RSV G protein into the pUC19 vector, has been digested by *MaeIII* and *HindIII*, and a 694 bp fragment has been isolated. Both fragments were then linked together by using 25 two complementary *BglII-MaeIII* synthetic linkers (Fig6A) and were inserted into the *EcoRI-HindIII* sites of pUC19 vector leading to pNIV4103 (Fig6B). The chimeric module was then retrieved from the pUC19 vector by a *BamHI-HindIII* digestion. After treating the protruding ends with the Klenow polymerase, the chimeric cassette has been inserted into the *SmaI* site of pSFV1 vector. The 30 resulting plasmid pNIV4106, thus contains the sequence coding for amino acids 1 to 492 of the F protein of PIV3 followed by amino acids 69 to 298 of the G protein of RSV inserted into the pSFV1 vector (Fig6C).

d) The PIV3 fusion protein lacking the membrane anchor domain linked to the MuV hemagglutinin-neuraminidase lacking the signal-anchor domain, F_{PIV3} (1-493) HN_{MuV} (60-582).

5

Plasmid pNIV3310 (see supra, FHN_{PIV3} in pIBI) was digested by *EcoRI* and *BglII* and a 1435 bp fragment was isolated. Plasmid pNIV3229 (see supra, HN_{MuV} into pUC19) was digested by *BbsI* and *HindIII*, and a 1610 bp fragment was isolated.

Both fragments were linked together by adding two synthetic complementary linkers

- 10 specifying a *BglII* and a *BbsI* ends (Fig7A) into the pUC19 vector leading to pNIV4117 (Fig7B). After sequencing the junction region, the chimeric cassette was retrieved from the pUC19 vector by a *BamHI* digestion and was inserted into the *BamHI* site of the pSFV1 vector. The resulting plasmid pNIV4118 encodes, cloned in the pSFV1 vector, the DNA sequence specifying amino acids 1 to 493 of the
15 PIV3 fusion protein linked to amino acids 60 to 582 of the MuV HN protein (Fig7C).

e) The MuV fusion protein lacking its membrane anchor domain linked to the RSV attachment protein lacking its signal-anchor domain, F_{MuV} (1-482) G_{RSV}

20 (69-298).

Plasmid pNIV3221, described in WO9425600 which carries the sequence encoding amino acids 1 to 462 of the MuV fusion protein within the pUC19 vector, has been digested with *EcoRI* and *BsrFI*, and a 771 bp fragment has been purified. Plasmid

- 25 pNIV3221 has been also digested with *BsrFI* and *PstI*, and a 628 bp fragment has been isolated. Plasmid pNIV2850 (see supra, G_{RSV} into the pUC19) has been digested with *MaeIII* and *HindIII* and a 694 bp fragment has been isolated. The three fragments were linked together; the F_{MuV}/G_{RSV} junction was created by adding to the ligation reaction two synthetic complementary oligonucleotide specifying *PstI*
30 and *MaeIII* sites (Fig8A), and were inserted into the *EcoRI-HindIII* sites of the pBluescript vector leading to pNIV4113(Fig8B). The chimeric cassette was recovered from pNIV4113 by a *Asp718I* digestion and, after treating the protruding

ends with the Klenow polymerase, was inserted into the *SmaI* site of the pSFV1 vector. The resulting plasmid, pNIV4114 contains into the pSFV1 vector the sequence specifying amino acids 1 to 482 of the MuV F protein linked to amino acids 69 to 298 of the RSV G protein (Fig8C).

5

f) The MuV fusion protein lacking its membrane anchor domain linked to the PIV3 hemagglutinin-neuraminidase lacking its signal-anchor domain, F_{MuV} (1-482) HN_{PIV3} (54-572).

10 Plasmid pNIV4113 (see supra, F_{MuV} x G_{RSV} in pBluescript) was digested by *BsaI* and *BamHI*, a 1469 bp fragment was isolated. Plasmid pNIV3308, described in WO9306218 and which carries the DNA sequence specifying amino acids 1 to 31 followed by amino acids 54 to 572 of the PIV3 HN protein into the pIBI vector, was digested by *EcoRI* and *BamHI* and a 1569 bp fragment was isolated. Both
15 fragments were linked together by two synthetic complementary linkers specifying *BsaI* and *EcoRI* sites (Fig9A) into the *BamHI* site of pBluescript leading to pNIV4115 (Fig9B). The chimeric module was recovered from pNIV4115 by a *BamHI* digestion and was inserted into *BamHI* site of pSFV1 vector. The resulting plasmid, pNIV4116, encodes, in the pSFV1 vector, the sequence specifying amino
20 acids 1-482 of the MuV F protein fused to amino acids 54 to 572 of the PIV3 HN protein (Fig9C).

g) The RSV fusion protein lacking its membrane anchor domain linked to the RSV attachment protein lacking its signal-anchor domain, F_{RSV} (1-526) G_{RSV} (69-298).

Plasmid pNIV2857 (Fig16A), a derivative of pNIV2841 and which contains the DNA sequence coding for amino acids 1 to 526 of the RSV fusion protein linked to amino acids 69 to 298 of the RSV attachment protein, has been digested by *Asp718I* and *HindIII* and a 2180 bp fragment has been isolated. After treating the protruding extremities with Klenow's polymerase, this fragment has been inserted in the *SmaI* site of the pSFV1 vector. The resulting plasmid pNIV2870, contains in the pSFV1

vector, the DNA sequence coding for amino acids 1 to 526 of the RSV fusion protein linked to amino acids 69 to 298 of the RSV attachment protein (Fig16B).

II) For transfection into CHO cells

5

a) The RSV fusion protein lacking the membrane anchor domain fused to the MuV hemagglutinin-neuraminidase lacking the signal-anchor domain, F_{RSV} (1-526) HN_{MuV} (60-582).

10 Plasmid pNIV4102, (Fig10A, see supra, F_{RSV} x HN_{MuV} into the pUC19 vector) has been digested with *Bam*HI, and after treating the protruding ends with the Klenow polymerase, the chimeric module has been inserted into the *Sma*I site of the glutamine synthetase (GS) vector, pEE14 (Cockett *et al*, 1990, Bio/Technology 8, 662-667). The resulting plasmid pEE14 F^{s+a-} RSV x HN s-a- MuV contains sequences coding for amino acids 1 to 526 of the RSV F protein fused to amino acids 60 to 582 of the MuV HN protein under the control of the major immediate early promoter of the human cytomegalovirus (hCMV-MIE) (Fig10B).

15 b) The RSV fusion protein lacking its membrane anchor domain linked to the PIV3 hemagglutinin-neuraminidase lacking its signal-anchor domain, F_{RSV} (1-526) HN_{PIV3} (70-572).

20 Plasmids pNIV4105 and pNIV4109 (Fig11A and B, see supra, F_{RSV} x HN_{PIV3} into the pUC19 vector) were digested by *Eco*RI and *Xba*I and a 2032 bp as well as a 25 1064 bp fragments were isolated. Both fragments were inserted together into the *Eco*RI site of pEE14. The resulting plasmid pEE14 F^{s+a-} RSV x HNs-a- PIV3 contains sequences coding for amino acids 1 to 526 of the RSV F protein fused to amino acids 70 to 572 of the PIV3 HN protein under the control of the hCMV promoter (Fig11C).

30

c) The PIV3 fusion protein lacking the membrane anchor region linked to the RSV attachment protein lacking the signal-anchor domain, F_{PIV3} (1-492) G_{RSV} (69-298).

5 Plasmid pNIV4103 (Fig12A, see supra, $F_{PIV3} \times G_{RSV}$ into the pUC19 vector) was digested by *Hind*III and a 2180 bp fragment was isolated. After treating the protruding extremities with the Klenow polymerase, the chimeric module was inserted into the *Sma*I site of the pEE14 vector. The resulting plasmid, pEE14 Fs^+a^- PIV3 $\times Gs^-a^-$ RSV, contains, under the control of the hCMV promoter, the sequence 10 encoding amino acids 1 to 492 of the PIV3 F protein followed by amino acids 69 to 298 of the RSV G protein (Fig 12B).

d) The PIV3 fusion protein lacking the membrane anchor domain fused to the MuV hemagglutinin-neuraminidase lacking the signal-anchor domain, F_{PIV3} (1-15) HN_{MuV} (60-582).

Plasmid pNIV4117 (Fig13A, see supra, $F_{PIV3} HN_{MuV}$ into the pUC19 vector) was digested with *Hind*III and a 3119 bp fragment was isolated and inserted into the *Hind*III site of the pEE14 vector. The resulting plasmid, pEE14 Fs^+a^- PIV3 $\times HNs^-a^-$ MuV, contains under the control of the hCMV promoter a sequence encoding 20 amino acids 1 to 493 of the PIV3 fusion protein fused to amino acids 60 to 582 of the MuV HN protein (Fig13B).

e) The MuV fusion protein lacking its membrane anchor domain fused to the 25 RSV attachment protein lacking its signal-anchor domain, F_{MuV} (1-482) G_{RSV} (69-298).

Plasmid pNIV4113 (Fig14A, see supra, $F_{MuV} G_{RSV}$ into the pBluescript vector) has been digested *Asp718I*, the protruding ends have been treated by the Klenow 30 polymerase. A 2200 bp fragment has been isolated and inserted into the *Sma*I site of pEE14. The resulting plasmid, pEE14 Fs^+a^- MuV $\times Gs^-a^-$ RSV, has, under the

control of the hCMV promoter, the sequence encoding amino acids 1 to 482 of the MuV F protein followed by amino acids 69 to 298 of the RSV G protein (Fig14B).

- 5 f) The MuV fusion protein lacking its membrane anchor domain fused to the
PIV3 hemagglutinin-neuraminidase lacking its signal-anchor domain, F_{MuV} (1-
482) HN_{PIV3} (54-572).

Plasmid pNIV4115 (Fig15A, see supra, F_{MuV} x HN_{PIV3} into the pBluescript vector)
has been digested with *EcoRI* and a 3040 bp fragment has been inserted into the
10 *EcoRI* site of the pEE14 vector. The resulting plasmid, pEE14 $Fs^+a^- MuV \times HNs^-a^-$
PIV3, contains, downstream to the hCMV promoter region, a sequence coding for
amino acids 1 to 482 of the MuV F protein followed by amino acids 54 to 572 of
the PIV3 HN protein (Fig15B).

- 15 g) The RSV fusion protein lacking its membrane anchor domain linked to the
RSV attachment protein lacking its signal-anchor domain, F_{RSV} (1-526) G_{RSV} (69-
298).

Plasmid pNIV2857 (Fig17A), a derivative of pNIV2841 and which contains the
20 DNA sequence coding for amino acids 1 to 526 of the RSV fusion protein linked to
amino acids 69 to 298 of the RSV attachment protein, has been digested by *Asp718I*
and *HindIII* and a 2180 bp fragment has been isolated. After treating the protruding
extremities with Klenow's polymerase, this fragment has been inserted the *SmaI* site
of the pEE14vector. The resulting plasmid, pEE14 $Fs^+a^- RSV \times Gs^-a^- RSV$, contains
25 under the control of the hCMV promoter the DNA sequence coding for amino acids
1 to 526 of the RSV fusion protein linked to amino acids 69 to 298 of the RSV
attachment protein (Fig17B).

- 30 h) The original RSV fusion protein lacking the membrane anchor domain
linked to the PIV3 hemagglutinin-neuraminidase lacking the signal-anchor
domain, F_{RSV} (1-526) HN_{PIV3} (70-572) bis.

Plasmid pNIV2852, a derivative of pNIV2820 which carries the DNA encoding the RSV F protein where the translation initiation site is in a more favourable context according to the model proposed by Kozak (Kozak M, Nature 308, 241-246, 1984), has been digested *BamHI* and *BspHI*, and a 1588 bp fragment has been isolated.

5

Plasmid pIBI-HN, a cDNA clone containing the complete coding sequence of the HN protein of PIV3 (received from Dr. K. Dimock, University of Ottawa, Canada) has been digested by *AseI* and *BamHI* and a 1468 bp has been isolated.

- 10 Both fragments were linked together by two complementary synthetic *BspHI-AseI* adaptators (Fig18A) and were inserted into the *BamHI* site of the pUC19 vector leading to pNIV4120 (Fig18B).

- 15 After the sequencing of the junction region, the chimeric cassette was retrieved by a *BamHI* digestion from pNIV4120 and inserted into the *BamHI* compatible *BclI* site of the pEE14 vector. The resulting plasmid pEE14 F^{s+}a⁻RSV x HNs^{a-}PIV3 bis contains the sequences coding for amino acids 1 to 526 of the RSV F protein fused to amino acids 70 to 572 of the PIV3 HN protein under the control of the hCMV promoter (Fig18C).

20

- This construct differs from the earlier pEE14 F^{s+}a⁻RSV x HNs^{a-}PIV3 construct (II-a) in the F coding region. In F_{RSVHN_{PIV3}} bis, the nucleic acid sequence found in F_{RSVHN_{PIV3}}, ATG GAT CTG (those codons are specifying aa Met1, Asp2 and Leu3) and ACC AGT (specifying aa Thr54 and Ser 55) is replaced by the original sequence of the RSV F protein that is ATG GAG TTG (specifying aa Met1, Glu2, Leu3) and ACT AGT (specifying Thr54 and Ser55).

- 25 i) The original RSV fusion protein lacking the membrane anchor domain linked to the PIV3 hemagglutinin-neuraminidase lacking the signal-anchor domain with, at the C-terminal part, a polyhistidine tail preceded by the enterokinase cleavage site, F_{RSV} (1-526) HN_{PIV3} (70-572) en his

Plasmid pIBI-HN, a cDNA containing the PIV3 HN protein coding sequence (see supra) has been digested by *PstI* and *SphI*. A 4588 bp fragment has been isolated and linked to complementary synthetic *PstI-SphI* adaptors (Fig19A).

- 5 After the sequencing of the junctions as well as the synthetic linkers, the resulting plasmid pNIV3340 has been digested by *XhoI* and *BamHI* and a 1121 bp fragment has been isolated (Fig19B).

- 10 Plasmid pNIV4120 (see supra) has been digested by *XhoI* and *BamHI* and a 2017 bp fragment has been isolated (Fig19C).

Both fragments were linked together and inserted into the *BamHI* compatible *BclI* site of the pEE14 vector. The resulting plasmid pEE14 FRSVs^{+a-} x HNs^{-a+} en his contains, under the control of the hCMV promoter, sequences coding for amino acids 1 to 526 of the RSV fusion protein fused to the amino acids 70-572 of the PIV3 HN protein fused to the enterokinase cleavage site, ({Asp} x4 Lys) followed by a polyhistidine tail ({his}x6) and a stop codon (Fig19D).

- 20 j) The signal domain of the tissue plasminogen activator fused to the yeast ubiquitin followed by the enterokinase cleavage recognition site and the original RSV fusion protein lacking its membrane signal and anchor domains linked to the PIV3 hemagglutin-neuraminidase lacking the signal-anchor domain, sTPA(1-21) UB(1-74) ent F_{RSV} (24-526) HN_{PIV3} (70-572)bis.

25

- 1) The signal domain of the tissue plasminogen activator fused to the yeast ubiquitin.

A 208 bp fragment corresponding to amino acid 1 to 76 of the ubiquitin protein of 30 *Saccharomyces cerevisiae* was isolated by a digestion of pNIV3475 (a derivative of YEPUBSTUALL, a yeast 2 μ vector backbone carrying the yeast ubiquitin) with *BamHI* and *XbaI* (Fig 20A).

- Plasmid JW4304 (received from J. Mullins, University of Washington, U.S.A) which encodes the signal domain of the tissue plasminogen activator (sTPA) was digested by *NheI* and *BamHI* and a 5115bp was isolated. Both fragments were linked together using two synthetic complementary *NheI-XbaI* adaptators (Fig20B). The resulting plasmid pNIV4121 was digested by *HindIII* and *BamHI*. A 330 bp fragment was isolated and inserted into the *HindIII* and *BamHI* sites of the pBluescript vector. The resulting plasmid pNIV4122 contains the DNA sequence specifying the signal domain of the tissue plasminogen activator followed by an alanine and a serine residue (those two amino acids are known to produce a good leader cleavage) fused to the yeast ubiquitin (Fig 20C).
- 2) The signal domain of the tissue plasminogen activator linked to the yeast ubiquitin followed by the enterokinase cleavage recognition site and amino acid 24 to 55 of the original fusion protein of RSV.
- Plasmid pNIV4122 (Fig 21A, see supra) was digested by *AflII* and *SpeI*. A 3212 bp fragment was isolated and linked to synthetic complementary *AflII-SpeI* adaptors (Fig21B). The entire module was then sequenced. The resulting plasmid pNIV4123 encodes the signal domain of the tissue plasminogen activator linked to the N-terminal 74 aa of the yeast ubiquitin followed by the recognition site of enterokinase {(Asp)4 Lys} and amino acid 24 to 55 of the original fusion protein of RSV (Fig21C).
- 3) The signal domain of the tissue plasminogen activator linked to the yeast ubiquitin followed by the enterokinase cleavage recognition site and the RSV fusion protein linked to the PIV3 hemagglutin-neuraminidase lacking their membrane domains.
- Plasmid pNIV4123 (Fig 22A, see supra) was digested by *HindIII*, treated by the Klenow polymerase and digested by *SpeI*. A 408 bp fragment has been isolated.

Plasmid pNIV4120 (Fig 22B, see supra) has been digested by *XbaI*, treated by the Klenow polymerase, and digested by *SpeI*. A 5620 bp fragment has been isolated.

Both fragment have been linked together to generate pNIV4124 (Fig 22C).

5

The entire coding module was retrieved from pNIV4124 by a digestion with *XbaI* and *EcoRI* and was inserted into the *XbaI* and *EcoRI* sites of the pEE14 expression vector. The resulting plasmid pEE14 sTPA x UBI x EN x F_saRSV x HNs'aPIV3, contains, under the control of the hCMV promoter, the sequence coding for aa1-21
10 of the tissue plasminogen activator followed by an alanine and a serine residue, by the 74 N-terminal amino acids of the yeast ubiquitin, by the recognition cleavage site of the enterokinase ({Asp}4 Lys), by aa 24-526 of the original RSV fusion protein and by aa 70-572 of the hemagglutin-neuraminidase of PIV3.

15 III) For transfection into Insect Cells

a) The original RSV fusion protein lacking the membrane anchor domain linked to the PiV3 hemagglutin-neuraminidase lacking the signal-anchor domain, F_{RSV} (1-526) HN_{PiV3} (70-572) bis.

20

Plasmid pNIV4120 (FIG 23A) was digested by *BamHI* and a 3114 bp fragment was isolated and inserted into the *BamHI* site of the baculovirus transfer vector, pAcUW51 (PharMingen). The resulting plasmid pNIV4132 (Fig 23B) contains, under the control of the polyhedrin promoter, the sequence coding for amino acids
25 1-526 of the RSV F protein fused to amino acids 70-572 of the PiV3 HN protein.

b) The baculovirus gp67 signal peptide fused to the original RSV fusion protein lacking both membrane signal and anchor domain linked to the PiV3 hemagglutin-neuraminidase lacking the signal-anchor domain, sGP67F_{RSV} (25-
30 526) HN_{PiV3} (70-572) bis.

Plasmid pNIV4120 (FIG 24A, see supra) was digested by *BamHI* and *SpeI* and a 2939 bp fragment was isolated, linked to two complementary synthetic *BamHI-SpeI* adaptors and inserted into the *BamHI* site of the baculovirus transfer vector, pAcGP67A (PharMingen). The resulting plasmid pNIV4136 (Fig 24) contains, 5 under the control of the polyhedrin promoter, the sequence coding for amino acids 1-38 of the Baculovirus gp67 protein, followed by an Alanine and an Aspartate linked to amino acids 25-526 of the RSV F protein fused to amino acids 70-572 of the PiV3 HN protein.

10 **Expression in eukaryotic cells**

A) via the pSFV1 vector

The pSFV1 vector is based on the Semliki Forest Virus (SFV) replicon. The DNA 15 of interest is cloned into the pSFV1 vector that serves as a template for *in vitro* synthesis of recombinant RNA. The RNA is transfected into mammalian cells such as BHK-21 cells. The recombinant RNA in the cells drives its own replication and capping resulting in production of heterologous protein.

20 Plasmids pNIV2870 was digested with *PvuII*; pNIV4106, pNIV4110, pNIV4114, pNIV4116 and pNIV4118 were digested with *SpeI* prior to RNA transcription. After a phenol extraction followed by an ethanol precipitation, 2 µg of linearized DNA was used as a template for RNA production. About 5 µg RNA was used to transfect, by electroporation, about 8 10⁶ BHK-21 cells. All experimental 25 procedures for RNA production and cell transfection are detailed in Liljestrom and Garoff (Bio/Technology, 1991, 9, 1356).

After 24 h to 48 h post-electroporation, cells and spent culture medium have been collected for ELISA and radioimmunoprecipitation assays.

30 a) pNIV4104, F_{RSV} HN_{MuV}

ELISA were done using mAb 2072 anti-HN MuV (Örvell, 1984, *J. Immunology* 132, 2622-2629) or 20RG45, a goat anti-RSV serum (Fitzgerald, U.S.A.) to coat the microtiter plates and a rabbit polyclonal anti-SBL-1 (MuV) serum or mAb19 anti-F RSV (G.Taylor, Inst. of Animal Health, Compton Lab., U.K.) as capture antibody.

Radioimmunoprecipitation of the 35 S-methionine labelled product was done using mAb2072 (Örvell) and products were resolved onto 7.5% SDS-PAGE.

10 b) pNIV4110, F_{RSV} HN_{PIV3}

ELISA were done using anti-RSV goat serum 20RG45 or mAb anti-HN_{PIV3} 4830 (Rydbeck *et al*, *J. Gen. Virol.* 67, 1531-1542, 1986) to coat microtiter plates and mAb19 anti-F RSV (G.Taylor) or rabbit anti-PIV3 (E.Norrby, Stockholm) serum as a capture antibody.

Radioimmunoprecipitation was done using anti-HN PIV3 mAb4830.

20 c) pNIV4106, F_{PIV3} G_{RSV}

ELISA were done using mAb anti-F_{PIV3} 4549 (E.Norrby, Stockholm) or mAb anti G_{RSV} 858-2 (Chemicon, U.S.A.) to coat microtiter plates and a rabbit anti-PIV3 serum as a capture antibody.

25 Radioimmunoprecipitation was done using mAb anti-F_{PIV3} 3283 (Behringwerke).

d) pNIV4118, F_{PIV3} HN_{MuV}

30 ELISA plates were coated with anti-F PIV3 mAb 1031215 (Norrby) or with mAb 2072 anti-HN MuV (Örvell) and rabbit anti-PIV3 sera or rabbit anti-MuV sera were used as capture antibody.

Immunoprecipitation of labelled product was done using mAb 2072 anti-HN MuV.

e) pNIV4114, F_{MuV} x G_{RSV}

ELISA plates were coated with anti-F MuV monoclonal 5414 (Örvell) or anti G_{RSV} mAb (Chemicon) and a rabbit anti-SBL-1 serum was used as a capture antibody.

f) pNIV4116, F_{MuV} x HN_{PIV3}

ELISA plates were coated with anti-F MuV mAb 5414 (Örvell) or mAb anti-HN PIV3 4830 (Norrby) and rabbit anti-SBL-1 serum or a rabbit anti-PIV3 serum as a capture antibody.

g) pNIV2870, F_{RSV}x G_{RSV}

ELISA were done using 20RG45, a goat anti-RSV serum (Fitzgerald, U.S.A.) to coat the microtiter plates and mAb19 anti-F RSV (G.Taylor, Inst. of Animal Health, Compton Lab., U.K.) as capture antibody.

20 B) Expression in CHO cells (stable transformants)

All recombinant plasmids were transfected by calcium phosphate coprecipitation into CHO-KI cells, using 20 µg DNA per 1.25 10⁶ cells. The CHO-KI cells were grown in GMEM-S medium. The GS transfectants were selected by adding 25 µM methionine sulfoximine to the culture medium two days after transfection. After ten to fourteen days, resistant colonies were picked and transferred into 96 wells plates. Each transformant was then transferred into 24 wells plates and subsequently to 80 cm² flasks. The GS transformants were assayed for the recombinant products when cells reached about 80% confluence. The procedure follows the one described in Cockett *et al* (Bio/Technology, 1990, 8, 662-667).

ELISA and immunoprecipitation of radiolabelled products were done using the same procedures as the ones described above for the pSFV1 system.

Expression in Insect cells

10 a) Expression in lepidopteran cells.

The vector pAcUW51 is a shuttle vector for bacteria and lepidopteran cells. A heterologous protein coding sequence can be inserted downstream the baculovirus p10 promoter or either downstream the polyhedrin promoter.

15

The pAcGP67 vector is a shuttle vector for bacteria and lepidopteran cells that contains the gp67 signal sequence upstream a multiple cloning site. A heterologous gene can be inserted in one of the cloning site and will be expressed as a gp67

signal peptide fusion protein under the control of the polyhedrin promoter. The gp67 signal peptide mediates the secretion of the recombinant protein.

- Either pAcUW51 or pAcGP67 recombinant plasmid can be transfected along with
- 5 baculovirus linearised DNA into Sf9 cells (Baculogold DNA, PharMingen). This leads to the generation of a recombinant baculovirus stock. The expression of the recombinant heterologous protein is obtained by infecting insect cells with the recombinant baculovirus
- 10 Plasmid pNIV4132 or plasmid pNIV4136 were transfected with baculovirus linearised DNA into Sf9 cells. Recombinant baculovirus 3546 (derived from cells transfected by pNIV4132) or 5V (derived from cells transfected by pNIV4136) were plaque purified and were used to infect Sf9 or High Five™ cells (Invitrogen). 24h to 72 h post-infection the cells and the spent culture medium have been collected for ELISA and
- 15 Western blot analysis.

ELISA were done using anti-RSV goat serum 20RG45 (Fizgerald) to coat microtiter plates and mAb19 anti-F RSV (G.Taylor) as a capture antibody.

- 20 Western blots were done using mAb19 anti-F RSV (G.Taylor) or using anti-RSV goat polyclonal serum 20RG45 (Fizgerald).

The spent medium from cells infected by either baculovirus 3546 or by 5V tested positive in ELISA. The level of expression, depending on the host cell line (SF9 or

25 High Five), multiplicity of infection, medium (fetal calf serum supplemented or serum free synthetic medium) was at least ten times higher than the one obtained with a recombinant CHO-KI clone obtained by transfection with pEE14 F_{RSV} (1-526) HN_{PIV3} (70-572)bis .

- 30 In addition, the spent medium of the baculovirus infected cells reacted positively in Western blot. A band in the vicinity of 110kDa was present in the immunoblots. These

results confirm the secretion of the chimeric F_{RSV}-HN_{PIV3} into the medium of SF9 and High Five cells infected with the recombinant baculoviruses.

b) Purification of the recombinant product

5

SF9 cells, adapted to serum free medium, were infected with the plaque purified recombinant baculovirus V5 or 3546. The cells were grown in suspension in 500ml Erlenmeyer flask in SF900II medium (Gibco BRL). The medium from virus infected cells were harvested two days post-infection. The soluble F_{RSV}-HN_{PIV3} product was
10 purified from the medium of infected cells by immunoaffinity chromatography using an anti-F RSV monoclonal antibody, mAb19. The anti-F monoclonal antibody was coupled to Activated CH Sepharose 4B (Pharmacia) following the manufacturer instructions. The immunoaffinity gel was washed 3 times with 10 bed volumes of buffer A (20mM phosphate buffer pH 6.4, NaCl 150mM) prior to sample loading.
15 After 16 hours at 4°C, the gel was washed with buffer A and the chimeric product was eluted with 100mM phosphoric acid. Eluted protein was neutralized immediately with one tenth of volume of 1M phosphate buffer pH 7.

SDS-PAGE of the immunoaffinity-purified F_{RSV}-HN_{PIV3} revealed the presence of a
20 major protein band of about 110 kDa. This protein was visualized by Coomassie blue staining of the gel and reacted with the monoclonal antibody anti-F_{RSV} (mAb19) or with the polyclonal serum (20RG45) on immunoblots (Fig25).

c) production of polyclonal antibodies

25

In order to obtain specific antibodies, the baculovirus derived F_{RSV}-HN_{PIV3} protein, purified by immunoaffinity as described above, was used to immunise four BalbC mice and two New Zealand white rabbits. Three sub-cutaneous injections of 20µg/ml/dose/rabbit or 6µg/100µl/dose/mouse were done at three weeks interval. The
30 sera were collected 3 weeks after the second and the third injection and the antibody response was detected using ELISA and Western blots assays.

1) ELISA assays

a) Mice response

The antibody response was followed using a goat anti-RSV serum (2ORG45, Fitzgerald, USA) to coat the microtiter plates and mouse anti-HN sera as capture

5 antibody. The antigens used were either the Fa_{RSV}-Drosophila or CHO derived, the F_{RSV}-HN_{PiV3} expressed in baculovirus and the medium of CHO cells transfected by the pEE14 was used as a negative control.

3 out of 4 mice sera collected after the second injection showed some but low

10 specific response. However, the mice sera collected after the third injection showed a high increase in level of specific antibodies.

b) Rabbit response

The antibody response was followed using either one of the following ELISA. The

15 antigens were the same as the one used to detect the mice antibody response.

Either a goat anti-RSV serum (2ORG45, Fitzgerald, USA), either a monoclonal antibody directed against the RSV fusion protein (mAb19, Compton Lab, UK) or a monoclonal antibody directed against the PiV3 hemagglutinin-neuraminidase

(mAb3285, Behring) were used to coat the microtiter plate and the rabbit anti-HN sera

20 was used as a capture antibody. The first and the second test bleeds generated high specific antibodies.

2) Western blot assays

Recombinant Fa-RSV CHO-KI ou Drosophila derived, F_{RSV}-HN_{PiV3} baculovirus

25 derived or the CHO-pEE14 spent medium culture were electrophoresed onto a 15%

SDS-PAGE and transferred onto a nitrocellulose membrane (Amersham). The rabbit

anti-HN sera as well as the mouse anti-HN sera detected specifically either the F

protein or the F_{RSV}-HN_{PiV3} chimera.

Example 2

- i) Optimization of the codon usage of the nucleic acids sequence coding for the RSV fusion protein lacking the membrane anchor domain linked to the PiV3 hemagglutin-neuraminidase lacking the signal-anchor domain, F_{RSV} (1-526)
5 HN_{PiV3} (70-572) for the expression in mammalian cells.

A table showing the comparison of the codon usage found in the F_{RSV}HN_{PiV3} module with the one found in highly expressed human gene can be found in Fig.26. As noted, the most prevalent codons found in the F_{RSV}HN_{PiV3} module have an A or a T
10 at their third degenerative position, whereas the human prevalent codons have a C or a G. For the improvement of the F_{RSV}HN_{PiV3} protein expression, the entire coding sequence has been re-engineered to fit at best the human codon usage. The re-engineered sequence was obtained using synthetic long oligonucleotides, polymerase chain reaction (PCR) and conventional cloning procedures.

15

Re-engineering of the coding sequence of the F_{RSV}HN_{PiV3} module

The entire synthetic sequence was recovered by joining three PCR fragments (A, B and C). The general strategy to obtain each PCR fragment is schematically represented in Fig 27. It consists of assembling overlapping long oligonucleotides in
20 a first round amplification. The resulting full size fragment is further amplified using two short primers located on each of its extremities.

Construction of fragment A

The first PCR fragment, corresponding to 18 bases encoding restriction sites
25 followed by bases 1 to 1269 of the F_{RSV}HN_{PiV3} followed by 8 bases encoding restriction sites, was obtained by PCR assembly of 18 overlapping oligonucleotides (Fig 28). This fragment has been inserted in the pCRIITOPO cloning vector (Invitrogen). After sequencing the fragment, it was retrieved from the pCRIITOPO vector by a *Xba*I and *Bsr*G I digestion and inserted into the corresponding sites of
30 pNIV4120. The module corresponding to F_{RSV}HN_{PiV3} with bases 1 to 1264 humanized was then retrieved by an *Xba*I and *Eco*RI digestion and inserted into the corresponding sites of pEE14 (Fig.29) generating pEE14xF_{RSV}humHN_{PiV3}.

Construction of fragment B

The second PCR fragment B corresponding to 13 bases encoding unique restriction sites followed by bases 1264 to 2136 of $F_{RSV}HN_{PiV3}$ was obtained by assembling 10 oligonucleotides whose sequences can be found in Fig.30. This fragment has been 5 inserted in the pCRIITOPO vector and sequenced. This fragment has been recovered by a *BsrGI* and *KpnI* digestion.

Construction of fragment C

The third PCR fragment corresponding to bases 2023 to 3090 followed by 6 extra 10 bases encoding an EcoRI site has been assembled starting from the 15 oligonucleotides shown in Fig 31. This fragment has been inserted in the pCRIITOPO cloning vector and sequenced. This fragment has been retrieved by a *KpnI* and *EcoRI* digestion (Fig 31).

15 Construction of the entire coding sequence

The entire $F_{RSV}HN_{PiV3}$ codon optimized coding sequence has been obtained by assembling fragment A, B, C as shown in Fig.32. pNIV4120 in which the PCR fragment A has replaced the original sequence (see Fig.29) was digested by *BsrGI* and *EcoRI*. The original sequence was eliminated and replaced by the *BsrGI*- *KpnI* 20 fragment B and the *KpnI*-*EcoRI* fragment C. The codon optimized module was retrieved from the PCRIITOPO vector by a *XbaI* and an *EcoRI* and inserted in the corresponding sites of the pEE14 vector. The resulting plasmid, pEE14 F_{RSV} hum HN_{PiV3} hum, encodes for the entire humanized coding sequence. The humanized $F_{RSV}HN_{PiV3}$ nucleic acids sequence is shown in Fig. 33.

25

Expression in CHO-KI cells

The recombinant pEE14 F_{RSV} hum HN_{PiV3} (see construction of fragment A, above, or 30 recombinant pEE14 F_{RSV} hum HN_{PiV3} hum see construction of the entire coding sequence, above) was transfected using the FuGene reagent (Boeringer Mannheim), using 5 μ g DNA per $1.25 \cdot 10^6$ cells. The CHO-KI cells were grown in GMEM-S medium. The GS transfectants were selected by adding 25 μ M methionine sulfoximine to the culture medium two days after transfection. After ten to fourteen

days, resistant colonies were picked and transferred into 96 wells plates. Each transformant was then transferred into 24 wells plates and subsequently to 80 cm² flasks. The GS transformants were assayed for the recombinant product when cells reached about 80% confluency. The procedure follows the one described in Cockett 5 *et al* (Bio/Technology, 1990, 8, 662-667). Alternatively, the expression was evaluated three to five days after the addition of sodium butyrate (2mM) in the cell culture.

To compare the expression level to that of the non humanized F_{RSV}HN_{PIV3}, ELISA 10 assays were done, using 20RG45, a goat anti-RSV serum (Fizgerald, U.S.A.) to coat the microtiter plates and mAb19 anti-F RSV (G. Taylor, Inst. of Animal Health, Compton Lab, U.K.) as capture antibody. The expression level was estimated using a purified Fa-RSV expressed in the Drosophila system.

15 The level of expression of the non-humanized expressed product by pEE14F_{RSV}HN_{PIV3} didn't exceed 0.03 mg/L and 0.1 mg/L when sodium butyrate was added to the culture medium. The level of expression of the partially humanized product expressed by pEE14F_{RSV} humHN_{PIV3}, reached 1 mg/L and up to 3 mg/L when sodium butyrate was added in the culture medium. The humanization 20 of the sequence coding for amino acids 1-423 of the 1029 amino acids thus enhanced the level of expression up to 30 fold (see Figure 34a).

The level of expression of the entirely humanized product expressed by pEE14F_{RSV} humHN_{PIV3}hum was at least of 2 mg/L and reached up to 50 mg/L when sodium 25 butyrate was added in the culture medium. The humanization of the entire coding region of F_{RSV}HN_{PIV3} thus enhanced the level of expression of at least 200 to 500 fold (see Figure 34b).

30 ii) Optimization of the codon usage of the nucleic acids sequence coding for the mumps virus (MuV) fusion protein lacking the membrane anchor domain linked to the measles virus (MV) lacking the signal-anchor domain, F_{Muv} (1-482) H_{Mv} (59-617) for the expression in mammalian cells.

A table showing the comparison of the codon usage found in the $F_{MuV}H_{MV}$ module with the one found in highly expressed human gene can be found in Fig.35. As it can be seen, the codon usage frequencies of this chimerical gene is quite different from those prevalent in the human genome. For the improvement of the $F_{MuV}H_{MV}$ protein expression, the entire coding sequence has been re-engineered to fit at best the human codon usage. The re-engineered sequence was obtained using synthetic long oligonucleotides, polymerase chain reaction (PCR) and conventional cloning procedures.

10

Re-engineering of the coding sequence of the $F_{MuV}H_{MV}$ module

The entire synthetic sequence was recovered by joining four PCR fragments (A, B, C and D). The general strategy to obtain each PCR fragment is schematically represented in Fig 36. It consists of assembling overlapping long oligonucleotides in a first round amplification. The resulting full size fragment is further amplified using two short primers located on each of its extremities.

Construction of fragment A

The first PCR fragment, corresponding to 13 bases specifying restriction sites and a Kozak consensus motif followed by bases 1 to 1026 of the $F_{MuV}H_{MV}$ was obtained by PCR assembly of 12 overlapping oligonucleotides (Fig 37). This fragment has been inserted in the pCRIITOPO cloning vector (Invitrogen). After sequencing the fragment, it was retrieved from the pCRIITOPO vector by a *XbaI* and *TspRI* digestion and a 963 bp fragment was further purified, leading to fragment A.

25

Construction of fragment B

The second PCR fragment B corresponding to bases 965 to 1712 of $F_{MuV}H_{MV}$ was obtained by assembling 9 oligonucleotides whose sequences can be found in Fig.38. After its insertion into the pCRIITOPO vector and its sequencing, this 785 bp fragment has been recovered by a *TspRI* and *AvaI* digestion.

Construction of fragment C

The third PCR fragment C corresponding to bases 1712 to 2485 has been assembled starting from the 11 oligonucleotides shown in Fig 39. It has been inserted in the pCRIITOPO cloning vector and sequenced. This 774 bp fragment has been retrieved
5 by an *Aval* and *Apal* digestion.

Construction of fragment D

The fourth PCR fragment D corresponding to bases 2485 to 3139 followed by 8 bp specifying a unique restriction site has been assembled starting from the 8
10 oligonucleotides shown in Fig 40. This fragment has been inserted in the pCRIITOPO vector and sequenced. A 657 bp fragment has been recovered after an *Apal* and *EcoRI* digestion.

Construction of the entire coding sequence

15 The entire $F_{Muv}H_{Mv}$ codon optimised coding sequence has been obtained by assembling fragment A, B, C, D and inserting the module digested by *XbaI* and *EcoRI* into the corresponding sites of the pEE14 vector (Fig. 41). The resulting plasmid, pEE14 F_{Muv} hum H_{Mv} hum, encodes for a humanised sequence coding for aa
1-482 of the mumps virus fusion protein followed by aa 59-617 of the measles
20 virus. The humanised and original $F_{Muv}H_{Mv}$ nucleic and amino acids sequences are shown in Fig. 42.

iii) Purification and analysis of FHN expressed in CHO-KI**25 a) Purification**

CHO cell line expressing secreted recombinant FHN was cultivated in cell factories in G-MEM medium supplemented with 2% FCS, in presence or absence of 1% Butyrate Na. FHN was purified by immunoaffinity chromatography by loading spent culture medium onto a Mab19-sepharose column as described using the same experimental
30 conditions.

When expressed in absence of Butyrate Na, purified FHN migrated on SDS-PAGE, in heating and reducing conditions, mainly as a band of 110 kDa. In contrast, FHN is visualized as a triplet of 110, 120 and 130 kDa when CHO cells are cultivated with butyrate. Heating has a more drastic effect than reducer on the FHN electrophoretic migration. Indeed, high molecular weight species are clearly detected in the preparation when electrophoresis proceeded without heating suggesting the presence of FHN aggregates or oligomers. These aggregates did not seem to be contaminated by CHO proteins. Antibodies directed to CHO proteins did not specifically recognize on Western blot any bands. Glycan analysis was performed using several lectins specific for different carbohydrate moieties. Surprisingly, FHN did not carry sialic acids or high-mannose structures but carbohydrates of galactose-acetyl-galactosamine type characteristic of hybrid N- and/or O-glycosylations.

N-terminal microsequence analysis showed mainly the presence of F1 subunit in bands of 110-130kDa. The F2 N-terminal amino acid sequence detected in bands of lower and higher molecular weight indicated that some purified FHN molecules are present under a F0 form (non mature F).

The presence of aggregates or oligomers in the FHN preparations was confirmed by gel filtration analysis and proteins were detected by laser-light scattering. Whatever the culture conditions (butyrate or not), between 50 and 65% of FHN populations displayed a molecular weight higher than 10^6 Da demonstrating that FHN is aggregated. 5 to 15% has a molecular weight ranging from 400 to 900 kDa whereas 30 to 35% is monomeric FHN.

25

b) Serum immunoglobulin analysis.

Immunisation protocol

The F_{RSV}HN_{PiV3} protein was purified from the spent medium culture of the CHO-KI cells transfected by the recombinant pEE14 F_{RSV}humHN_{PiV3}hum by immunoaffinity chromatography as described (Purification of the recombinant product expressed in baculovirus recombinant infected SF9 cells). The product was injected in 7 groups of Balb C1 mice as described in the following table 1.

Humoral response directed against the FHN protein

The humoral response directed against the FHN protein was determined. To this end, ELISA plates were coated with immunoaffinity purified FHN protein.

5

Total IgG (Fig 43)

To detect specific anti-FHN total IgG, ELISA plates were coated with 200ng of immunoaffinity purified FHN protein, plates were then saturated and dilutions of the mice second bleed sera were then applied. Total IgG were detected using a biotinylated serum directed against mouse IgG.

10

IgG1 (Fig 44)

To detect specific anti-FHN IgG1, ELISA plates were coated with 100ng of immunoaffinity purified FHN protein, plates were then saturated and dilutions of the mice second bleed sera were then applied. IgG1 were detected using a biotinylated serum directed against mouse IgG1.

15

IgG2a (Fig 45)

To detect specific anti-FHN IgG2a, ELISA plates were coated with 100ng of immunoaffinity purified FHN protein, plates were then saturated and dilutions of the mice second bleed sera were then applied. IgG2a were detected using a biotinylated serum directed against mouse IgG2a.

20

The titer of each sera was determined and a mean titer for each group was calculated and is reported in table 2. These experiments show that the FHN antigen by itself or formulated with adjuvant (group 1 to 3), stimulates a specific humoral response. Indeed, no anti-FHN antibodies are generated in the untreated mice group (group 5) or in the group immunised solely with the adjuvant (group 4). The group 1 (and group 4) adjuvant was 3D-MPL and QS21 formulated with cholesterol containing liposomes as described in WO 96/33739; the group 2 adjuvant was alum.

25

The IgG1/IgG2a ratio indicates the Th1 or Th2 orientation of the immune response; (Table 2), a protective response against both the RSV or the PiV3 should tend toward

the Th1 type, that is a low IgG1/IgG2a ratio. In this regard, the responses generated with the FHN formulated in the presence of the 3D-MPL + QS21 adjuvant appears to be the more promising one.

5 **Table 1:** Experimental procedures

Immunogenicity FHN in
mice

Group	n	Vol (µl)	route	Antigen		Immuno- stimulants	buffer	preservative
				nature	dose (µg)			
1	12	2x50	IM	FHN	2	3D-MPL/ QS21	PBS mod pH 7.4	thiomersal low (1 µg/ml)

Claims

1. A process for preparing a heterochimeric protein or an immunogenic derivative thereof comprising an immunogenic fragment of the fusion (F) protein of RSV, PIV1, PIV2, PIV3, MV or MuV and an immunogenic fragment of the attachment (G, HN or H) protein of RSV, PIV1, PIV2, PIV3, MV or MuV which process comprises expressing recombinant DNA encoding the heterochimeric protein or immunogenic derivative thereof in CHO cells and recovering the protein.
2. A process according to claim 1 wherein at least one non-preferred or less preferred codon in a natural gene or DNA encoding the said heterochimeric protein or immunogenic fragment thereof has been replaced by a preferred codon encoding the same amino acid.
3. A heterochimeric protein or an immunogenic derivative thereof comprising an immunogenic fragment of the fusion (F) protein of RSV, PIV1, PIV2, PIV3, MV or MuV and an immunogenic fragment of the attachment (G, HN or H) protein of RSV, PIV1, PIV2, PIV3, MV or MuV, with the proviso that where one of the immunogenic fragments is derived from RSV F, RSV G or PIV3 F, PIV3 HN, the other of the immunogenic fragments is derived from MuV F, MuV HN, MV F, MV H, PIV1 F, PIV1 HN, PIV2 F or PIV2 HN.
4. A process for preparing a heterochimeric protein or immunogenic derivative thereof as claimed in claim 3 which process comprises expressing recombinant DNA encoding the heterochimeric protein or immunogenic derivative thereof in either one of; CHO cells or insect cells and recovering the protein.
5. A protein according to claim 3 wherein the immunogenic fragment of the F protein is lacking the membrane anchor domain at its C-terminal end.
- 30 6. A protein according to claims 3 or 5 wherein the immunogenic fragment of the G, HN or H protein is lacking the signal/anchor domain at its N-terminal end.

7. A protein according to any one of claims 3, 5 or 6 which is linked via an amino acid in the C-terminal part of the immunogenic fragment of the F protein of RSV, PIV1, PIV2, PIV3, MV or MuV to an amino acid in the N-terminal part of the immunogenic fragment of the G protein of RSV or the HN protein of PIV1, PIV2,

5 PIV3, MuV or the H protein of MV.

8. A protein according to any one of claims 3, 5, 6 or 7 which commences at its N-terminal end with a signal sequence from the F protein of RSV, PIV1, PIV2, PIV3, MV or MuV.

10

9. A protein according to any one of claims 3, 5, 6 or 7 which commences at its N-terminal end with a signal sequence from TPA.

10. A protein according to any one of claims 3 or 5 to 8 which comprises a

15 ubiquitin leader sequence.

11. A protein according to any one of claims 3 or 5 to 9 which comprises a polyhistidine tail.

20 12. A protein according to claim 10 or 11 which comprises a cleavage site for cleaving off the ubiquitin leader sequence and/or the polyhistidine tail.

13. A heterochimeric protein according to any one of claims 3 or 5 to 11 which is selected from the group consisting of:

25 $F_s^+ a^- RSV x HNs^- a^- MuV;$
 $F_s^+ a^- PIV3 x HNs^- a^- MuV;$
 $F_s^+ a^- MuV x Gs^- a^- RSV;$ or
 $F_s^+ a^- MuV x HNs^- a^- PIV3,$ or
an immunogenic derivative thereof.

30

14. A heterochimeric protein according to any one of claims 3 or 5 to 11 which is selected from the group consisting of:

F_s⁺a⁻MuV x Hs⁺a⁻MV; or
F_s⁺a⁻RSVx HNs⁺a⁻PIV1, or
F_s⁺a⁻RSVx HNs⁺a⁻PIV2, or
an immunogenic derivative thereof.

5

15. A heterochimeric protein which is:

F_s⁺a⁻(1-526) RSV x HNs⁺a⁻(70-572) PIV3,
F_s⁺a⁻(1-492) PIV3 x Gs⁺a⁻(69-298) RSV,
F_s⁺a⁻(1-526) RSV x HNs⁺a⁻(70-572) PIV3 bis,

10 F_s⁺a⁻(1-526) RSV x HNs⁺a⁻(70-572) PIV3 ent his, or

sTPA (1-21) UB (1-74) ent F_s⁺a⁻(24-526) x HNs⁺a⁻(70-572) PIV3, or
an immunogenic derivative thereof.

16. Recombinant DNA encoding a heterochimeric protein or an immunogenic

15 derivative thereof according to any one of claims 3 or 5 to 15.

17. Recombinant DNA according to claim 16 in which at least one non-preferred
or less preferred codon in the DNA has been replaced by a preferred codon
encoding the same amino acid.

18. DNA which hybridises under conditions of high stringency with the DNA of
20 claim 16 or 17.

19. An expression vector comprising recombinant DNA according to claims 16 to
18.

20. A host transformed with DNA according to any one of claims 16 to 18 or with
a vector according to claim 19.

25 21. A host according to claim 20 which is a CHO cell.

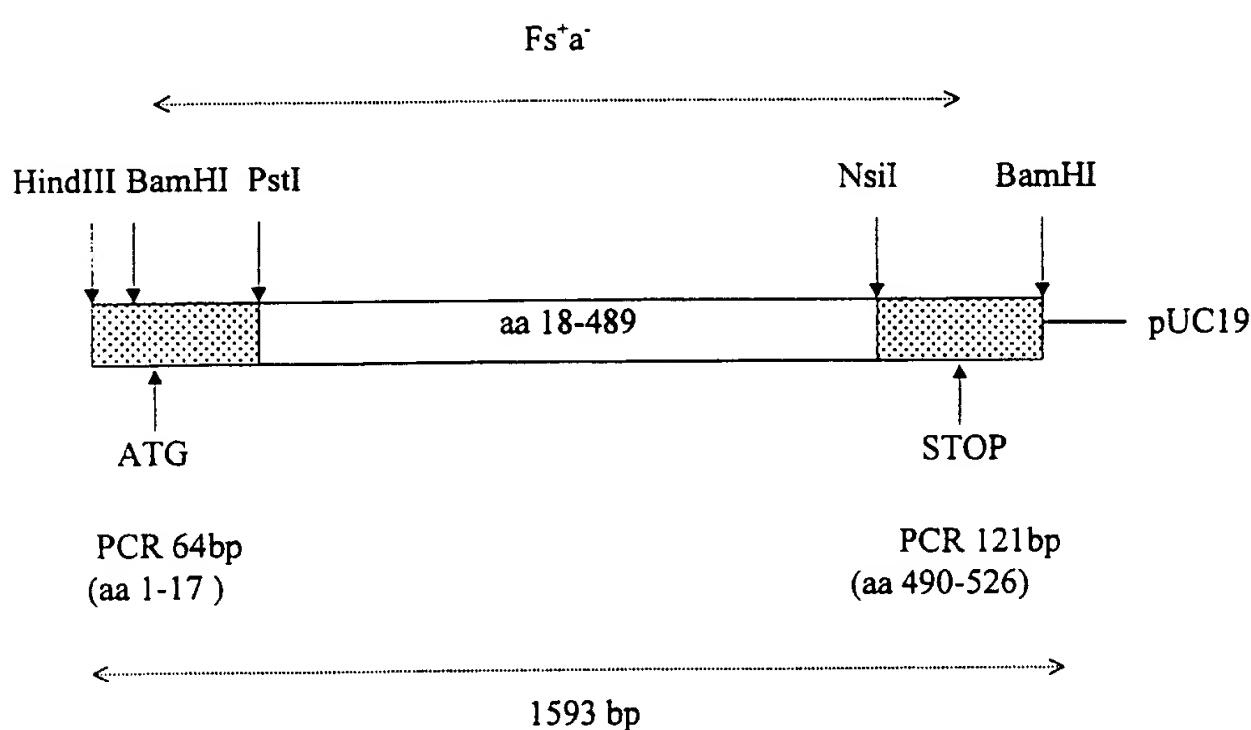

22. A host according to claim 21 which is an insect cell.

23. A vaccine composition comprising a protein according to any one of claims 3 or 5 to 13 or an immunogenic derivative thereof in admixture with a pharmaceutically acceptable carrier.
24. A vaccine composition according to claim 23 further comprising 3D
5 Monophosphoryl lipid A and/or QS-21.
25. A vaccine composition according to claims 23 or 24 wherein the carrier is an oil-in-water emulsion.
26. A heterochimeric protein or an immunogenic derivative thereof according to any one of claims 3 or 5 to 15 for use in medicine.
- 10 27. A process for the production of a heterochimeric protein according to any one of claims 3 or 5 to 15 which process comprises expressing recombinant DNA encoding said protein or immunogenic fragment thereof in a host cell and recovering the protein.
- 15 28. A method of treating a human or animal susceptible to paramyxoviridae viral infections comprising administering an effective amount of a vaccine according to any one of claims 23 to 25.
29. Use of a protein or an immunogenic derivative thereof according to any one of claims 3 or 5 to 15 in the manufacture of a medicament for use in the treatment of respiratory disorders.
